

GitHub repo uses IDIR for authentication (requiring multifactor identification).

GitHub actions are used to build and deploy to OpenShift.

Branch protection rules are enabled to prevent direct commits to main. Developers must commit their changes to a branch, and only approved reviewers can merge the changes into main.

Uses a Pull Request (PR) pipeline:

- \* Creating a PR will deploy to the dev namespace.
- \* Merging to main will trigger an approval to test and production environments.
- \* Only approved users can approve a promotion to test, and production.
